Homework 2

Wenhe Li (wl1508)

Problem 1

a

$$P(A|B) = rac{P(A \cap B)}{P(B)}$$
 $P(B|A) = rac{P(A \cap B)}{P(A)}$

Given above equation:

$$P(B|A)P(A) = P(A|B)P(B) \Rightarrow P(A|B) = \frac{P(B|A)P(A)}{P(B)}$$

b

$$P(A, B, C) = P(A)P(B|A)P(C|A, B)$$

- c By defination, $\mathbb{E}[x]=P(A)*X_1+(1-P(A))*X_2$, where $X_1=1$ and $X_2=0$. Therefore, $\mathbb{E}[x]=P(A)$
- d
- o i

From the table:

$$P(X = 1) = \frac{7}{18}, P(X = 1|Y = 0) = \frac{3}{8}$$

 $P(X = 1) \neq P(X = 1|Y = 0)$

Not independent.

 \circ ii $P(X=1|Y=1,Z=1)=\frac{1}{3}=P(X=1|Y=0,Z=1)=P(X=1|Z=1)\\P(X=1|Y=1,Z=0)=\frac{1}{2}=P(X=1|Y=0,Z=0)=P(X=1|Z=0)\\ \text{Independent.}$

$$\circ$$
 iii $P(X=0|X+Y>0)=rac{5}{12}$

Problem 2

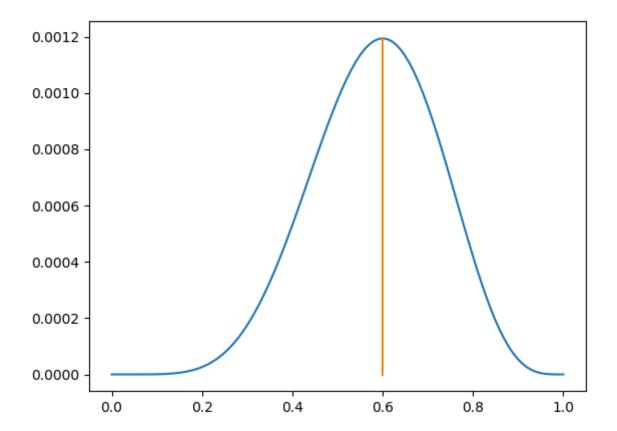

a

$$L(\hat{ heta}) = \prod_{i=1}^n heta^{x_i} * (1- heta)^{(1-x_i)}$$

Not depend on the order.

b

```
import matplotlib.pyplot as plot
def mle(D, theta):
    res = 1
    for d in D:
        res *= ((theta ** d) * ((1 - theta) ** (1 - d)))
    return res
if __name__ == "__main__":
    D = [1] * 6 + [0] * 4
    init = 0
    xAxis = []
    yAxis = []
    maxX = 0
    maxY = 0
    while init <= 1.01:
        xAxis.append(init)
        yAxis.append(mle(D, init))
        if yAxis[-1] > maxY:
            maxY = yAxis[-1]
            maxX = xAxis[-1]
        init += .01
    plot.plot(xAxis, yAxis)
    plot.plot([maxX, maxX], [0, maxY])
    plot.show()
```

We define $n_1=\#of X_i=1$ and $n_2=\#of X_i=2$.

$$L(\hat{ heta}) = \prod_{i=1}^n heta^{x_i} st (1- heta)^{(1-x_i)} \Rightarrow L(\hat{ heta}) = heta^{n_1} st (1- heta)^{n_2}$$

By putting 1n on the equation:

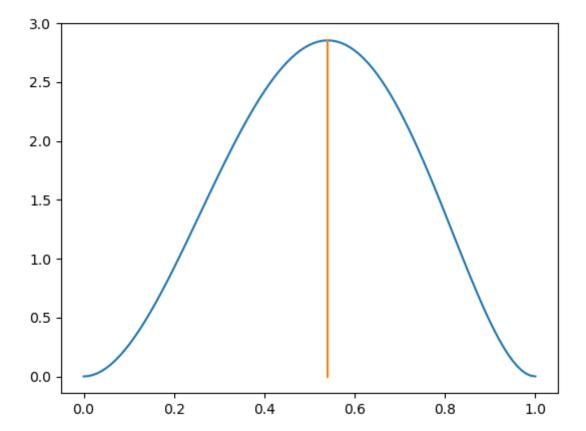

$$\ln L(\hat{ heta}) = n_1 \ln \theta + n_2 \ln (1- heta)$$

To find the argument that makes the function max, we derive it:

$$rac{d \ln L(\hat{ heta})}{d heta} = rac{n_1}{ heta} - rac{n_2}{1- heta} = 0 \ heta = rac{n_1}{n_1 + n_2}$$

It agrees with the plot.

```
import matplotlib.pyplot as plot
def mapFunc(D, theta):
    res = 1
    for d in D:
        res *= ((theta) ** d) + ((1 - theta) ** (1 - d))
        beta = ((theta ** 2)*(1 - theta) ** 2) / .0333
        return res * beta
if __name__ == "__main__":
    D = [1] * 6 + [0] * 4
    init = 0
    xAxis = []
    yAxis = []
    maxX = 0
    maxY = 0
    while init <= 1.01:
       xAxis.append(init)
       yAxis.append(mapFunc(D, init))
       if yAxis[-1] > maxY:
            maxY = yAxis[-1]
            maxX = xAxis[-1]
        init += .01
    plot.plot(xAxis, yAxis)
    plot.plot([maxX, maxX], [0, maxY])
    plot.show()
```

e

$$L(\hat{ heta})p(\hat{ heta}) = rac{ heta^{n_1+2}(1- heta)^{n_2+2}}{B(3,3)} \ rac{d\ln L(\hat{ heta})p(\hat{ heta})}{d heta} = rac{n_1+2}{ heta} - rac{n_2+2}{1- heta} \ heta = rac{n_1+2}{n_1+n_2+4}$$

It agreed with the plot.

- f $\label{eq:mle} \mbox{MLE is a specific case of MLA where its prior } p(\theta) \mbox{ is 1}$
- g As $n o \infty, \theta^{MAP} = \theta^{MLE}$. That is mainly becaseu that the prior distributation becomes less significant.
